

LCP1521S/LCP152DEE

ASD
(Application Specific Devices)

PROGRAMMABLE TRANSIENT VOLTAGE SUPPRESSOR FOR SLIC PROTECTION

FEATURES

- Dual programmable transient suppressor
- Wide negative firing voltage range:
 $V_{MGL} = -150\text{ V max.}$
- Low dynamic switching voltages:
 V_{FP} and V_{DGL}
- Low gate triggering current: $I_{GT} = 5\text{ mA max}$
- Peak pulse current: $I_{PP} = 30\text{ A (10/1000 }\mu\text{s)}$
- Holding current: $I_H = 150\text{ mA min}$
- Low space consuming package

DESCRIPTION

These devices have been especially designed to protect new high voltage, as well as classical SLICs, against transient overvoltages.

Positive overvoltages are clamped by 2 diodes. Negative surges are suppressed by 2 thyristors, their breakdown voltage being referenced to $-V_{BAT}$ through the gate.

These components present a very low gate triggering current (I_{GT}) in order to reduce the current consumption on printed circuit board during the firing phase.

BENEFITS

TRISILs™ are not subject to ageing and provide a fail safe mode in short circuit for a better protection. Trisils are used to help equipment to meet various standards such as UL60950, IEC950 / CSA C22.2, UL1459 and FCC part68. Trisils have UL94 V0 resin approved (Trisils are UL497B approved [file: E136224]).

TECHNICAL INFORMATION

Figure 5: LCP152 concept behavior

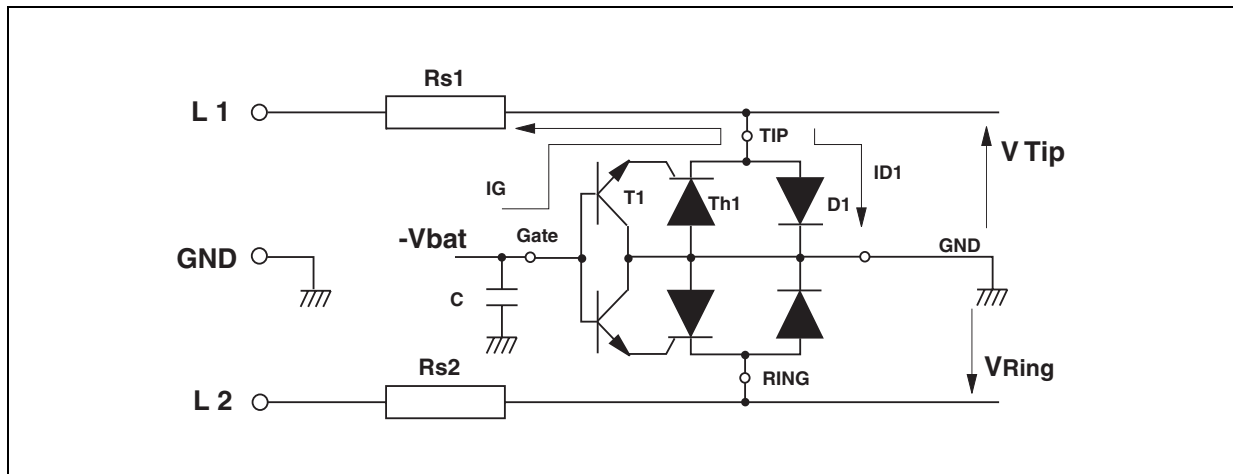

Figure 5 shows the classical protection circuit using the LCP152 crowbar concept. This topology has been developed to protect the new high voltage SLICs. It allows to program the negative firing threshold while the positive clamping value is fixed at GND.

When a negative surge occurs on one wire (L1 for example) a current I_G flows through the base of the transistor T1 and then injects a current in the gate of the thyristor Th1. Th1 fires and all the surge current flows through the ground. After the surge when the current flowing through Th1 becomes less negative than the holding current I_H , then Th1 switches off.

When a positive surge occurs on one wire (L1 for example) the diode D1 conducts and the surge current flows through the ground.

Figure 6: Example of PCB layout based on LCP152 protection

Figure 6 shows the classical PCB layout used to optimize line protection. The capacitor C is used to speed up the crowbar structure firing during the fast surge edges. This allows to minimize the dynamical breakover voltage at the SLIC Tip and Ring inputs during fast strikes. Note that this capacitor is generally present around the SLIC - Vbat pin. So to be efficient it has to be as close as possible from the LCP152 Gate pin and from the reference ground track (or plan) (see figure 6). The optimized value for C is 220nF.

The series resistors Rs1 and Rs2 designed in figure 5 represent the fuse resistors or the PTC which are mandatory to withstand the power contact or the power induction tests imposed by the various country standards. Taking into account this fact the actual lightning surge current flowing through the LCP is equal to:

$$I_{\text{surge}} = V_{\text{surge}} / (R_g + R_s)$$

With V_{surge} = peak surge voltage imposed by the standard.

R_g = series resistor of the surge generator

R_s = series resistor of the line card (e.g. PTC)

e.g. For a line card with 30Ω of series resistors which has to be qualified under GR1089 Core 1000V 10/1000μs surge, the actual current through the LCP152 is equal to:

$$I_{\text{surge}} = 1000 / (10 + 30) = \mathbf{25A}$$

The LCP152 is particularly optimized for the new telecom applications such as the fiber in the loop, the WLL, the remote central office. In this case, the operating voltages are smaller than in the classical system. This makes the high voltage SLICs particularly suitable.

The schematics of figure 7 on next page gives the most frequent topology used for these applications.
