LCD controller/driver

PCF2105

1 FEATURES

- Single chip Liquid Crystal Display (LCD) controller/driver
- 1 or 2-line display of up to 24 characters per line, or 2 or 4-line display of up to 12 characters per line
- 5 × 7 character format plus cursor; 5 × 8 for kana (Japanese syllabary) and user-defined symbols
- On-chip generation of intermediate LCD bias voltages
- On-chip oscillator requires no external components (external clock also possible)
- Display data RAM: 80 characters
- Character generator ROM: 240 characters
- Character generator RAM: 16 characters
- 4 or 8-bit parallel bus or 2-wire I²C-bus interface (400 kHz)
- CMOS and TTL compatible
- 32 row, 60 column outputs
- Multiplex (MUX) rates 1 : 32 and 1 : 16
- Uses common 11-code instruction set
- Logic supply voltage range: $V_{DD} - V_{SS} = 2.5$ to 6 V
- Display supply voltage range: $V_{DD} - V_{LCD} = 3.5$ to 9 V
- Low power consumption
- I²C-bus address selection (SA0): 011101.

2 APPLICATIONS

- Telecom equipment
- Portable instruments
- Point-of-sale terminals.

3 GENERAL DESCRIPTION

The PCF2105 integrated circuit is similar to the PCF2114x (described in the "PCF2116 family" data sheet) but does not contain the high voltage generator of that device.

4 ORDERING INFORMATION

TYPE NUMBER	PACKAGE		
	NAME	DESCRIPTION	VERSION
PCF2105MU/2	–	chip with bumps in tray	–

Furthermore, a fast I²C-bus interface (400 kHz) is provided.

The PCF2105 is optimized for chip-on-glass applications.

A specific letter code 'M' for a character set is programmed in the Character Generator ROM (CGROM) (see Fig.5).

The PCF2105 is a low power CMOS LCD controller/driver, designed to drive a split screen dot matrix LCD of 1 or 2 lines by 24 characters or 2 or 4 lines by 12 characters with a 5 × 8 dot format. All necessary functions for the display are provided in a single chip, including on-chip generation of LCD bias voltages which results in a minimum of external components and lower system power consumption. To allow partial V_{DD} shutdown the ESD protection system of the SCL and SDA pads does not use a diode connected to V_{DD} .

The chip contains a character generator and displays alphanumeric and kana characters. The PCF2105 interfaces to most microcontrollers via a 4 or 8-bit parallel bus, or via the 2-wire I²C-bus.

3.1 Packages

- PCF2105MU/2: chip with bumps in tray.

3.2 Available types

- PCF2105MU/2: character set 'M' in CGROM.

7 PAD FUNCTIONS

7.1 RS: Register Select (parallel control)

Bit RS selects the register to be accessed for read and write when the device is controlled by the parallel interface. RS = 0 selects the instruction register for write and the busy flag and address counter for read. RS = 1 selects the data register for both read and write. There is an internal pull-up resistor on pad RS.

7.2 R/ \overline{W} : read/write (parallel control)

R/ \overline{W} selects either the read (R/ \overline{W} = 1) or write (R/ \overline{W} = 0) operation when control is by the parallel interface. There is an internal pull-up resistor on pad R/ \overline{W} .

7.3 E: data bus clock (parallel control)

Pad E should be HIGH to signal the start of a read or write operation when the device is controlled by the parallel interface. Data is clocked in or out of the chip on the falling edge of the clock. Note that pad E must be connected to V_{SS} (logic 0) when I²C-bus control is used.

7.4 DB7 to DB0: data bus (parallel control)

The bidirectional, 3-state data bus transfers data between the system controller and the PCF2105. DB7 acts as the busy flag, signalling that internal operations are not yet completed. In 4-bit operations, DB7 to DB4 are used and DB3 to DB0 must be left open-circuit. There is an internal pull-up resistor on each of the data lines. Note that pads DB7 to DB0 must be left open-circuit when I²C-bus control is used.

7.5 C60 to C1: column driver outputs

Pads C60 to C1 output the data for pairs of columns. This arrangement permits optimized Chip-On-Glass (COG) layout for 4-line by 12 characters.

7.6 R32 to R1: row driver outputs

Pads R32 to R1 output the row select waveforms to the left and right halves of the display.

7.7 V_{LCD}: LCD power supply

Negative power supply for the liquid crystal display.

LCD controller/driver

PCF2105

7.8 OSC: oscillator

When the on-chip oscillator is used, pad OSC must be connected to V_{DD} . An external clock signal, if used, is input at pad OSC.

7.9 SCL: serial clock line

Pad SCL is input for the I²C-bus clock signal.

7.10 SDA: serial data line

Pad SDA is input/output for the I²C-bus data line.

7.11 SA0: address input

The hardware subaddress line is used to program the device subaddress for 2 different PCF2105s on the same I²C-bus.

7.12 T1: test input

Pad T1 must be connected to V_{SS} . Not user accessible.

8 FUNCTIONAL DESCRIPTION

Figure 1 shows the block diagram for the PCF2105. Details are explained in subsequent sections.

8.1 LCD bias voltage generator

The intermediate bias voltages for the LCD are generated on-chip. This removes the need for an external resistive bias chain and significantly reduces the system power consumption. The optimum levels depend on the multiplex (MUX) rate and are selected automatically when the number of lines in the display is defined.

The optimum value of the LCD operating voltage V_{OP} depends on the MUX rate, the LCD threshold voltage V_{th} and the number of bias levels. The relationships, together with the discrimination ratio (D) are given in Table 1.

Using a 5-level bias scheme for MUX rate 1 : 16 allows $V_{OP} < 5$ V for most LCDs. The effect on the display contrast is negligible.

Table 1 Optimum values for V_{OP}

MUX RATE	NUMBER OF BIAS LEVELS	$\frac{V_{OP}}{V_{th}}$	$D = \frac{V_{on}}{V_{off}}$
1 : 16	5	3.67	1.277
1 : 32	6	5.19	1.196

8.2 Oscillator

The on-chip oscillator provides the clock signal for the display system. No external components are required. Pad OSC must be connected to V_{DD} .

8.3 External clock

If an external clock is to be used, it must be input at pad OSC. The resulting display frame frequency is given

$$\text{by } f_{\text{frame}} = \frac{f_{\text{osc}}}{2304}$$

A clock signal must always be present, otherwise the LCD may be frozen in a DC state.

8.4 Power-on reset

The Power-on reset block initializes the chip after power-on or power failure.

8.5 Registers

The PCF2105 has two 8-bit registers, an Instruction Register (IR) and a Data Register (DR). The Register Select (RS) signal determines which register will be accessed.

The IR stores instruction codes such as 'clear display' and 'cursor shift', and address information for the DDRAM and CGRAM. The system controller can write data to but can not read data from the instruction register.

The DR temporarily stores data to be read from the DDRAM and CGRAM. When reading, data from the DDRAM or CGRAM (corresponding to the address in the address counter) is written to the DR prior to being read by the 'read data' instruction.

8.6 Busy flag

The Busy Flag (BF) indicates the free or busy status of the PCF2105. Bit BF = 1 indicates that the chip is busy and further instructions will not be accepted. The BF is output at pad DB7 when bit RS = 0 and bit $\overline{R/W}$ = 1. Instructions should only be written after checking that BF = 0 or waiting for the required number of clock cycles.

8.7 Address Counter (AC)

The AC assigns addresses to the DDRAM and CGRAM for reading and writing and is set by the instructions 'set CGRAM address' and 'set DDRAM address'. After a read/write operation the AC is automatically incremented or decremented by 1. The AC contents are output to the bus (pads DB6 to DB0) when bit RS = 0 and bit $\overline{R/W}$ = 1.

LCD controller/driver

PCF2105

8.8 Display Data RAM (DDRAM)

The DDRAM stores up to 80 characters of display data, represented by 8-bit character codes. DDRAM locations not used for storing display data can be used as general purpose RAM. The basic DDRAM-to-display mapping scheme is shown in Fig.2. With no display shift, the characters represented by the codes in the first 12 or 24 DDRAM locations, starting at address 00 in line 1, are displayed. Subsequent lines display data starting at addresses 20, 40, or 60 hexadecimal (hex). Figures 3 and 4 show the DDRAM-to-display mapping scheme when the display is shifted.

The address range for a 1-line display is 00 to 4F; for a 2-line display from 00 to 27 (line 1) and 40 to 67 (line 2); for a 4-line display from 00 to 13, 20 to 33, 40 to 53 and 60 to 73 for lines 1, 2, 3 and 4 respectively. For 2 and 4-line displays the end address of one line and the start address of the next line are not successive. When the display is shifted each line wraps around independently of the others (see Figs 3 and 4).

When data is written to the DDRAM, wrap-around occurs from 4F to 00 in 1-line display and from 27 to 40 and 67 to 00 in 2-line display; from 13 to 20, 33 to 40, 53 to 60 and 73 to 00 in 4-line display.

8.9 Character Generator ROM (CGROM)

The CGROM generates 240 character patterns in 5×8 dot format from 8-bit character codes. Figure 5 shows the character set currently available.

8.10 Character Generator RAM (CGRAM)

Up to 16 user-defined characters may be stored in the CGRAM. The CGROM and CGRAM use a common address space, of which the first column is reserved for the CGRAM (see Fig.5). Figure 6 shows the addressing principle for the CGRAM.

8.11 Cursor control circuit

The cursor control circuit generates the cursor (underline and/or character blink as shown in Fig.7) at the DDRAM address contained in the address counter. When the address counter contains the CGRAM address the cursor will be inhibited.

8.12 Timing generator

The timing generator produces the various signals required to drive the internal circuitry. Internal chip operation is not disturbed by operations on the data buses.

8.13 LCD row and column drivers

The PCF2105 contains 32 row drivers and 60 column drivers. They connect the appropriate LCD bias voltages in sequence to the display, in accordance with the data to be displayed. The bias voltages and the timing are selected automatically when the number of lines in the display is selected. Figures 8 and 9 show typical waveforms.

In the 1-line display (MUX rate 1 : 16), the row outputs are driven in pairs, for example R1/R17 and R2/R18.

This allows the output pairs to be connected in parallel, thereby providing greater drive capability.

Unused outputs should be left unconnected.

MGK847

Fig.5 Character set 'M' in CGROM.

LCD controller/driver

PCF2105

Character code bits 0 to 3 correspond to CGRAM address bits 3 to 6.
 CGRAM address bits 0 to 2 designate character pattern line position. The 8th line is the cursor position and display is performed by logical OR with the cursor. Data in the 8th line will appear in the cursor position.
 Character pattern column positions correspond to CGRAM data bits 0 to 4; bit 4 being at the left end, as shown in this figure.
 CGRAM character patterns are selected when character code bits 4 to 7 are all logic 0. CGRAM data is logic 1 corresponds to selection for display.
 Only bits 0 to 5 of the CGRAM address are set by the 'set CGRAM address' instruction. Bit 6 can be set using the 'set DDRAM address' instruction or by using the auto-increment feature during CGRAM write. All bits 0 to 6 can be read using the 'read busy flag and address' instruction.

Fig.6 Relationship between CGRAM addresses, data and display patterns.

LCD controller/driver

PCF2105

8.14 Programming of the MUX rate 1 : 16

With the MUX rate 1 : 16 the PCF2105 can be used in the following ways:

- To drive a 1-line display of 24 characters
- To drive a 2-line display of 12 characters, resulting in better contrast. The internal data flow of the chip is optimized for this purpose.

To program the MUX rate 1 : 16, bits M and N of the 'function set' instruction must be set to logic 0 (see Table 3). Figures 10, 11 and 12 show the DDRAM addresses of the display characters. The second row of each figure corresponds to either the right half of a 1-line display or to the second line of a 2-line display. Wrap around of data during display shift or when writing data is non-standard.

LCD controller/driver

PCF2105

8.15 Programming of the MUX rate 1 : 32

With the MUX rate 1 : 32 the PCF2105 can be used in the following ways:

- To drive a 2-line display of 24 characters, use instruction 'function set' to set bit M to logic 0 and bit N to logic 1
- To drive a 4-line display of 12 characters, use instruction 'function set' to set both bits M and N to logic 1.

8.16 Reset function

The PCF2105 automatically initializes (resets) when power is turned on. The state after reset is given in Table 2 (see Tables 3 and 4 for the description of the bits).

Table 2 State after reset

STEP	DESCRIPTION
1	clear display
2	function set: bit DL = 1: 8-bit interface bits M and N = 0: 1-line display bit G = 0: not used
3	display control: bit D = 0: display off bit C = 0: cursor off bit B = 0: blink off
4	entry mode set: bit I/D = 1: +1(increment) bit G = 0: not used
5	default address pointer to DDRAM; the busy flag indicates the busy state (BF = 1) until initialization ends; the busy state lasts 2 ms; the chip may also be initialized by software; see Tables 10 and 11.
6	I ² C-bus interface reset

9 INSTRUCTIONS

Only two PCF2105 registers, the Instruction Register (IR) and the Data Register (DR) can be directly controlled by the microcontroller. Before internal operation, control information is stored temporarily in these registers to allow interface to various types of microcontrollers which operate at different speeds or to allow interfacing to peripheral control ICs. The PCF2105 operation is controlled by the instructions shown in Table 3 together with their execution time. Details are explained in subsequent sections.

Instructions are of 4 categories, those that:

1. Designate PCF2105 functions such as display format, data length, etc.
2. Set internal RAM addresses
3. Perform data transfer with internal RAM
4. Others.

In normal use, category 3 instructions are used most frequently. However, automatic incrementing by 1 (or decrementing by 1) of internal RAM addresses after each data write lessens the microcontroller program load. The display shift in particular can be performed concurrently with display data write, thus enabling the designer to develop systems in minimum time with maximum programming efficiency.

During internal operation, no instruction other than the 'read busy flag and address' will be executed.

Because the busy flag is set to logic 1 while an instruction is being executed, it is advisable to ensure that the flag is set to logic 0 before sending the next instruction or wait for the maximum instruction execution time, as given in Table 3. An instruction sent while the busy flag is HIGH will not be executed.

9.1 Clear display

'Clear display' writes space code 20 (hexadecimal) into all DDRAM addresses (the character pattern for character code 20 must be a blank pattern), sets the DDRAM address counter to logic 0 and returns the display to its original position if it was shifted. Consequently, the display disappears and the cursor or blink position goes to the left edge of the display (the first line if 2 or 4 lines are displayed) and sets bit I/D of 'entry mode set' to logic 1 (increment mode). Bit S of 'entry mode set' does not change.

The instruction 'clear display' requires extra execution time. This may be allowed for checking the Busy Flag (BF) or by waiting until 2 ms has elapsed. The latter must be applied where no read-back options are available, as in some Chip-On-Glass (COG) applications.

9.2 Return home

'Return home' sets the DDRAM address counter to logic 0 and returns the display to its original position if it was shifted. DDRAM contents do not change. The cursor or blink position goes to the left of the display (the first line if 2 or 4 lines are displayed). Bits I/D and S of 'entry mode set' do not change.

LCD controller/driver

PCF2105

Table 3 Instructions (note 1)

INSTRUCTION	RS	R/W	DB7	DB6	DB5	DB4	DB3	DB2	DB1	DB0	DESCRIPTION	REQUIRED CLOCK CYCLES ⁽²⁾
NOP	0	0	0	0	0	0	0	0	0	0	no operation	0
Clear display	0	0	0	0	0	0	0	0	0	1	clears entire display and sets DDRAM address 00 in Address Counter (AC)	165
Return home	0	0	0	0	0	0	0	0	1	0	sets DDRAM address 00 in the AC; also returns shifted display to original position; DDRAM contents remain unchanged	3
Entry mode set	0	0	0	0	0	0	0	1	I/D	S	sets cursor move direction and specifies shift of display; these operations are performed during data write and read	3
Display control	0	0	0	0	0	0	1	D	C	B	sets entire display on/off (D), cursor on/off (C) and blink of cursor position character (B)	3
Cursor/display shift	0	0	0	0	0	1	S/C	R/L	0	0	moves cursor and shifts display without changing DDRAM contents	3
Function set	0	0	0	0	1	DL	N	M	G	0	sets interface data length (DL), number of display lines (N, M) and voltage generator control (G); bit G is not used	3
Set CGRAM address	0	0	0	1	A _{CG}					sets CGRAM address	3	
Set DDRAM address	0	0	1	A _{DD}					sets DDRAM address	3		
Read busy flag and address	0	1	BF	A _C					reads BF indicating internal operation is being performed and reads AC contents	0		
Read data	1	1	read data					reads data from CGRAM or DDRAM	3			
Write data	1	0	write data					writes data to CGRAM or DDRAM	3			

Notes

- In the I²C-bus mode the DL bit is don't care. 8-bit mode is assumed. In the I²C-bus mode a control byte is required when bit RS or R/W is changed; control byte: Co, RS, R/W, 0, 0, 0, 0, 0; command byte: DB7 to DB0.
- Example: $f_{\text{osc}} = 150 \text{ kHz}$, $T_{\text{cy}} = \frac{1}{f_{\text{osc}}} = 6.67 \mu\text{s}$; 3 cycles = 20 μs ; 165 cycles = 1.1 ms.

LCD controller/driver

PCF2105

Table 4 Command bit identities, used in Table 3

BIT	LOGIC 0	LOGIC 1
I/D	decrement	increment
S	display freeze	display shift
D	display off	display on
C	cursor off	cursor on
B	character at cursor position does not blink	character at cursor position blinks
S/C	cursor move	display shift
R/L	left shift	right shift
DL	4 bits	8 bits
N (M = 0)	2 lines × 12 characters; MUX rate 1 : 16	2 lines × 24 characters; MUX rate 1 : 32
N (M = 1)	reserved	4 lines × 12 characters; MUX rate 1 : 32
BF	end of internal operation	internal operation in progress
Co	last control byte, only data bytes to follow	next two bytes are a data byte and another control byte

9.3 Entry mode set

9.3.1 I/D

When bit I/D = 1 (0), the DDRAM or CGRAM address increments (decrements) by 1 when data is written to or read from the DDRAM or CGRAM. The cursor or blink position moves to the right when incremented and to the left when decremented. The cursor and blink are inhibited when the CGRAM is accessed.

9.3.2 S

When bit S = 1, the entire display shifts either to the right (bit I/D = 0) or to the left (I/D = 1) during a DDRAM write. Consequently, it looks as if the cursor stands still and the display moves. The display does not shift when reading from the DDRAM, or when writing to or reading from the CGRAM. When S = 0 the display does not shift.

9.4 Display control

9.4.1 D

The display is on when bit D = 1 and off when D = 0. Display data in the DDRAM is not affected and can be displayed immediately by setting D to logic 1.

9.4.2 C

The cursor is displayed when bit C = 1 and inhibited when C = 0. Even if the cursor disappears, the display functions, I/D, etc. remain in operation during display data write. The cursor is displayed using 5 dots in the 8th line (see Fig.7).

9.4.3 B

The character indicated by the cursor blinks when bit B = 1. The blink is displayed by switching between display characters and all dots on with a period of 1 second when $f_{osc} = 150 \text{ kHz}$ (see Fig.7). At other clock frequencies the blink period is equal to $\frac{150 \text{ kHz}}{f_{osc}}$.

The cursor and the blink can be set to display simultaneously.

9.5 Cursor/display shift

'Cursor/display shift' moves the cursor position or the display to the right or left without writing or reading display data. This function is used to correct a character or move the cursor through the display. In the 2 or 4-line display, the cursor moves to the next line when it passes the last position of the line (40 or 20 decimal). When the displayed data is shifted repeatedly all lines shift at the same time; displayed characters do not shift into the next line. The Address Counter (AC) content does not change if the only action performed is shift display, but increments or decrements with the cursor shift.

LCD controller/driver

PCF2105

9.6 Function set

9.6.1 DL (PARALLEL MODE ONLY)

Bit DL sets the interface data length. Data is sent or received in bytes (DB7 to DB0) when DL = 1 or in two nibbles (DB7 to DB4) when DL = 0. When 4-bit length is selected, data is transmitted in two cycles using the parallel bus. In a 4-bit application DB3 to DB0 are left open (internal pull-ups).

DL can not be set to logic 0 from the I²C-bus interface. If DL has been set to logic 0 via the parallel bus, programming via the I²C-bus interface is complicated.

9.6.2 N AND M

Bits N and M set the number of display lines.

9.7 Set CGRAM address

‘Set CGRAM address’ sets bits 0 to 5 of the CGRAM address (A_{CG} in Table 3) into the AC (binary A[5] to A[0]). Data can then be written to or read from the CGRAM.

Only bits 0 to 5 of the CGRAM address are set by the ‘set CGRAM address’ instruction. Bit 6 can be set using the ‘set DDRAM address’ instruction or by using the auto-increment feature during CGRAM write. All bits 0 to 6 can be read using the ‘read busy flag and address’ instruction.

9.8 Set DDRAM address

‘Set DDRAM address’ sets the DDRAM address (A_{DD} in Table 3) into the AC (binary A[6] to A[0]). Data can then be written to or read from the DDRAM.

Table 5 Hexadecimal address ranges

ADDRESS	FUNCTION
00 to 4F	1 line of 24 characters
00 to 0B and 0C to 4F	2 lines of 12 characters
00 to 27 and 40 to 67	2 lines of 24 characters
00 to 13, 20 to 33, 40 to 53 and 60 to 73	4 lines of 12 characters

9.9 Read busy flag and address

‘Read busy flag and address’ reads the Busy Flag (BF). When bit BF = 1 it indicates that an internal operation is in progress. The next instruction will not be executed until BF = 0, so BF should be checked before sending another instruction.

At the same time, the value of the AC expressed in binary A[6] to A[0] is read out. The address counter is used by both CGRAM and DDRAM and its value is determined by the previous instruction.

9.10 Write data to CGRAM or DDRAM

‘Write data’ writes binary 8-bit data (D[7] to D[0]) to the CGRAM or the DDRAM.

Whether the CGRAM or DDRAM is to be written to is determined by the previous specification of CGRAM or DDRAM address setting. After writing, the address automatically increments or decrements by 1, in accordance with the ‘entry mode set’.

Only bits D[4] to D[0] of CGRAM data are valid, bits D[7] to D[5] are ‘don’t care’.

9.11 Read data from CGRAM or DDRAM

‘Read data’ reads binary 8-bit data D[7] to D[0] from the CGRAM or DDRAM.

The most recent ‘set address’ instruction determines whether the CGRAM or DDRAM is to be read.

The ‘read data’ instruction gates the content of the Data Register (DR) to the bus while pad E = HIGH. After E goes LOW again, internal operation increments (or decrements) the AC and stores RAM data corresponding to the new AC into the DR.

Remark: the only three instructions that update the DR are:

- ‘Set CGRAM address’
- ‘Set DDRAM address’
- ‘Read data’ from CGRAM or DDRAM.

Other instructions (e.g. ‘write data’, ‘cursor/display shift’, ‘clear display’, ‘return home’) will not change the data register content.

LCD controller/driver

PCF2105

10 INTERFACE TO MICROCONTROLLER (PARALLEL INTERFACE)

The PCF2105 can send data in either two 4-bit modes or one 8-bit mode and can thus interface to 4 or 8-bit microcontrollers.

In the 8-bit mode data is transferred as 8-bit bytes using the 8 data lines DB7 to DB0. The control lines E, RS, and R/W are required.

In the 4-bit mode data is transferred in two cycles of 4-bits each. The higher order bits (corresponding to DB7 to DB4

in 8-bit mode) are sent in the first cycle and the lower order bits (DB3 to DB0 in 8-bit mode) in the second cycle. Data transfer is complete after two 4-bit data transfers. It should be noted that two cycles are also required for the busy flag check. The 4-bit mode is selected by instruction. See Figs 13, 14 and 15 for examples of bus protocol.

In the 4-bit mode, the pads DB3 to DB0 must be left open-circuit. They are pulled up to V_{DD} internally.

Fig.13 4-bit transfer example.

PCF2105

11 INTERFACE TO MICROCONTROLLER (I²C-BUS INTERFACE)

11.1 Characteristics of the I²C-bus

The I²C-bus is for bidirectional, 2-line communication between different ICs or modules. The 2 lines are a serial data line (SDA) and a serial clock line (SCL). Both lines must be connected to a positive supply via a pull-up resistor. Data transfer may be initiated only when the bus is not busy.

11.2 Bit transfer

One data bit is transferred during each clock pulse. The data on the SDA line must remain stable during the HIGH-level period of the clock pulse as changes in the data line at this time will be interpreted as a control signal (see Fig.16).

11.3 START and STOP conditions

Both data and clock lines remain HIGH when the bus is not busy. A HIGH-to-LOW transition of the data line, while the clock is HIGH is defined as the START condition (S). A LOW-to-HIGH transition of the data line while the clock is HIGH is defined as the STOP condition (P) (see Fig.17).

11.4 System configuration

A device generating a message is a transmitter, a device receiving a message is the receiver. The device that controls the message is the master and the devices which are controlled by the master are the slaves (see Fig.18).

11.5 Acknowledge

The number of data bytes transferred between the START and STOP conditions from transmitter to receiver is unlimited. Each byte of 8 bits is followed by an acknowledge bit. The acknowledge bit is a HIGH signal put on the bus by the transmitter during which time the master generates an extra acknowledge related clock pulse. A slave receiver which is addressed must generate an acknowledge after the reception of each byte. Also a master receiver must generate an acknowledge after the reception of each byte that has been clocked out of the slave transmitter. The device that acknowledges must pull-down the SDA line during the acknowledge clock pulse, so that the SDA line is stable LOW during the HIGH period of the acknowledge related clock pulse (set-up and hold times must be taken into consideration). A master receiver must signal an end of data to the transmitter by not generating an acknowledge on the last byte that has been clocked out of the slave. In this event the transmitter must leave the data line HIGH to enable the master to generate a STOP condition (see Fig.19).

11.6 I²C-bus protocol

Before any data is transmitted on the I²C-bus, the device which should respond is addressed first. The addressing is always carried out with the first byte transmitted after the start procedure. The I²C-bus configuration for the different PCF2105 read and write cycles is illustrated in Figs 20, 21 and 22.

$V_{bias(tol)}$	bias voltage tolerance on pads R32 to R1 and C60 to C1	note 6	–	± 20	± 130	mV

Notes

- LCD outputs are open-circuit; inputs at V_{DD} or V_{SS} ; bus inactive; internal or external clock with duty factor 50%.
- Resets all logic when $V_{DD} < V_{POR}$.
- When the voltages are above V_{DD} or below V_{SS} , an input current may flow; this current must not exceed ± 0.5 mA.
- Tested on sample basis.
- Resistance of output terminals (R32 to R1 and C60 to C1) with load current $I_L = 150 \mu A$; $V_{OP} = V_{DD} - V_{LCD} = 9$ V; outputs measured one at a time.
- LCD outputs open-circuit.

15 AC CHARACTERISTICS

$V_{DD} = 2.5$ to 6.0 V; $V_{SS} = 0$ V; $V_{LCD} = V_{DD} - 3.5$ V to $V_{DD} - 9$ V; $T_{amb} = -40$ to $+85$ °C; unless otherwise specified.

t _{SU;STO}	set-up time for STOP condition		0.6	–	–	μs
C _L	load capacitance for each bus line		–	–	400	pF

Notes

1. V_{DD} = 5.0 V.
2. All timing values are valid within the operating supply voltage and ambient temperature range and are referenced to V_{IL} and V_{IH} with an input voltage swing of V_{SS} to V_{DD}.
3. C_L = total capacitance of one bus line in pF and R = 100 Ω.
4. A fast mode I²C-bus device can be used in a standard-mode I²C-bus system, but the requirement t_{SU;DAT} ≥ 250 ns must then be met. This will automatically be the case if the device does not stretch the LOW period of the SCL signal. If such a device does stretch the LOW period of the SCL signal, it must output the next data bit to the SDA line t_{r(max)} + t_{SU;DAT} = 1000 + 250 = 1250 ns (according to the standard-mode I²C-bus specification) before the SCL line is released.
5. A device must internally provide a hold time of at least 300 ns for the SDA signal (referred to the V_{IH(min)} of the SCL signal) in order to bridge the undefined region of the falling edge of SCL.
6. The maximum t_{HD;DAT} has only to be met if the device does not stretch t_{LOW} of the SCL signal.

LCD controller/driver**PCF2105**

17.1 4-bit operation, 2 × 12 display using internal reset

The program must set functions prior to 4-bit operation. Table 6 shows an example. When power is turned on, 8-bit operation is automatically selected and the PCF2105 attempts to perform the first write as an 8-bit operation. Since nothing is connected to DB3 to DB0, a rewrite is then required. However, since one operation is completed in two accesses of 4-bit operation, a rewrite is required to set the functions (see Table 6 step 3).

Thus, DB7 to DB4 of the 'function set' are written twice.

17.2 8-bit operation, 2 × 12 display using internal reset

Table 7 shows an example of a 1-line display in 8-bit operation. The PCF2105 functions must be set by the 'function set' instruction prior to display. Since the DDRAM can store data for 80 characters, the RAM can be used for advertising displays when combined with display shift operation. Since the display shift operation changes the display position only DDRAM contents remain unchanged. Display data entered first can be displayed when the 'return home' instruction is performed.

17.3 8-bit operation, 2 × 24 display

For a 2-line display, the cursor automatically moves from the first to the second line after the 40th digit of the first line has been written. Thus, if there are only 8 characters in the first line, the DDRAM address must be set after the 8th character is completed (see Table 8). It should be noted that both lines of the display are always shifted together, data does not shift from one line to the other.

17.4 I²C-bus operation, 2 × 12 display

A control byte is required with most instructions (see Table 9).

17.5 Initializing by instruction

If the power supply conditions for correctly operating the internal reset circuit are not met, the PCF2105 must be initialized by instruction. Tables 10 and 11 show how this may be performed for 8-bit and 4-bit operation.

LCD controller/driver

PCF2105

Table 6 Example of 4-bit operation; 1-line display; using internal reset

STEP	INSTRUCTION	DISPLAY	OPERATION
1	power supply on (PCF2105 is initialized by the internal reset circuit)		initialized; no display appears
2	function set RS R/W DB7 DB6 DB5 DB4 0 0 0 0 1 0		sets to 4-bit operation; in this instance operation is handled as 8-bits by initialization and only this instruction completes with one write
3	function set RS R/W DB7 DB6 DB5 DB4 0 0 0 0 1 0 0 0 0 0 0 0		sets to 4-bit operation; selects 2 × 12 display
			4-bit operation starts from this point and resetting is needed
4	display control RS R/W DB7 DB6 DB5 DB4 0 0 0 0 0 0 0 0 1 1 1 0	–	turns display and cursor on
			entire display is blank after initialization
5	entry mode set RS R/W DB7 DB6 DB5 DB4 0 0 0 0 0 0 0 0 0 1 1 0	–	sets mode to increment the address by 1 and to shift the cursor to the right at the time of write to the DDRAM or CGRAM
			display is not shifted
6	write data to CGRAM or DDRAM RS R/W DB7 DB6 DB5 DB4 1 0 1 1 0 1 1 0 0 1 1 0	P_	writes 'P'; the DDRAM has already been selected by initialization at power-on
			the cursor is incremented by 1 and shifted to the right

STEP	INSTRUCTION	DISPLAY	OPERATION
12	write data to CGRAM or DDRAM	PHILIPS	sets mode for display shift at the time of write
	RS R \bar{W} DB7 DB6 DB5 DB4 DB3 DB2 DB1 DB0 0 0 0 0 0 0 0 1 1 1	MICROCO_	
13	write data to CGRAM or DDRAM	HILIPS	writes 'M'; display is shifted to the left; the first and second lines shift together
	RS R \bar{W} DB7 DB6 DB5 DB4 DB3 DB2 DB1 DB0 1 0 1 1 0 0 1 1 0 1	ICROCOM_	
14		 	
15	return home	PHILIPS	returns both display and cursor to the original position (address 0)
	RS R \bar{W} DB7 DB6 DB5 DB4 DB3 DB2 DB1 DB0 0 0 0 0 0 0 0 0 1 0	MICROCOM	

Table 9 Example of I²C-bus operation; 1-line display; using internal reset (assuming SA0 = V_{SS}); note 1

STEP	INSTRUCTION	DISPLAY	OPERATION
1	I ² C-bus start		initialized; no display appears
2	slave address for write		during the acknowledge cycle SDA will be pulled-down by the PCF2105
	SA6 SA5 SA4 SA3 SA2 SA1 SA0 R \bar{W} Ack 0 1 1 1 0 1 0 0 1		
3	send a control byte for function set		control byte sets RS and R \bar{W} for following data bytes
	Co RS R \bar{W} Ack 0 0 0 1		
4	function set		selects 1-line display; SCL pulse during acknowledge cycle starts execution of instruction
	DB7 DB6 DB5 DB4 DB3 DB2 DB1 DB0 Ack 0 0 1 X 0 0 0 0 1		
5	display control	–	turns display and cursor on; entire display shows character hexadecimal 20 (blank in ASCII-like character sets)
	DB7 DB6 DB5 DB4 DB3 DB2 DB1 DB0 Ack 0 0 0 0 1 1 1 0 1		
6	entry mode set	–	sets mode to increment the address by 1 and to shift the cursor to the right at the time of write to the DDRAM or CGRAM; display is not shifted
	DB7 DB6 DB5 DB4 DB3 DB2 DB1 DB0 Ack 0 0 0 0 0 1 1 0 1		

LCD controller/driver

PCF2105

STEP	INSTRUCTION	DISPLAY	OPERATION
7	I ² C-bus start	–	for writing data to DDRAM, RS must be set to logic 1; therefore a control byte is needed
8	slave address for write SA6 SA5 SA4 SA3 SA2 SA1 SA0 R/W Ack 0 1 1 1 0 1 0 0 1	–	
9	send a control byte for write data Co RS R/W Ack 0 1 0 1	–	
10	write data to DDRAM DB7 DB6 DB5 DB4 DB3 DB2 DB1 DB0 Ack 1 1 0 1 0 0 0 0 1	P_	writes 'P'; the DDRAM has been selected at power-up; the cursor is incremented by 1 and shifted to the right
11	write data to DDRAM DB7 DB6 DB5 DB4 DB3 DB2 DB1 DB0 Ack 1 1 0 0 1 0 0 0 1	PH_	writes 'H'
12 to 15		 	
16	write data to DDRAM DB7 DB6 DB5 DB4 DB3 DB2 DB1 DB0 Ack 1 1 0 1 0 0 1 1 1	PHILIPS_	writes 'S'
17	(optional I ² C-bus stop) I ² C-bus start + slave address for write (as step 8)	PHILIPS_	
18	control byte Co RS R/W Ack 1 0 0 1	PHILIPS_	
19	return home DB7 DB6 DB5 DB4 DB3 DB2 DB1 DB0 Ack 0 0 0 0 0 0 1 0 1	PHILIPS	sets DDRAM address 0 in AC; also returns shifted display to original position; DDRAM contents unchanged; this instruction does not update the DR
20	control byte for read Co RS R/W Ack 0 1 1 1	PHILIPS	DDRAM content will be read from following instructions; the R/W has to be set to logic 1 while still in I ² C-bus write mode
21	I ² C-bus start	PHILIPS	

LCD controller/driver

PCF2105

STEP	INSTRUCTION	DISPLAY	OPERATION
22	slave address for read SA6 SA5 SA4 SA3 SA2 SA1 SA0 R/W Ack 0 1 1 1 0 1 0 1 1	PHILIPS	during the acknowledge cycle the content of the DR is loaded into the internal I ² C-bus interface and to be shifted out; in the previous instruction neither a 'set address' nor a 'read data' has been performed; therefore the content of the DR was unknown
23	read data: 8 × SCL + master acknowledge; note 2 DB7 DB6 DB5 DB4 DB3 DB2 DB1 DB0 Ack X X X X X X X X 1	PHILIPS	8 × SCL; content loaded into interface during previous acknowledge cycle and shifted out over SDA; MSB is DB7; during master acknowledge content of DDRAM address 01 is loaded into the I ² C-bus interface
24	read data: 8 × SCL + master acknowledge; note 2 DB7 DB6 DB5 DB4 DB3 DB2 DB1 DB0 Ack 0 1 0 0 1 0 0 0 0	PHILIPS	8 × SCL; code of letter 'H' is read first; during master acknowledge code of letter 'I' is loaded into the I ² C-bus interface
25	read data: 8 × SCL + no master acknowledge; note 2 DB7 DB6 DB5 DB4 DB3 DB2 DB1 DB0 Ack 0 1 0 0 1 0 0 1 1	PHILIPS	no master acknowledge; after the content of the I ² C-bus interface register is shifted out no internal action is performed; no new data is loaded to the interface register; DR is not updated; AC is not incremented and cursor is not shifted
26	I ² C-bus stop	PHILIPS	

Notes

1. X = don't care.
2. SDA is left at high-impedance by the microcontroller during the READ acknowledge.

19 DEFINITIONS

Data sheet status	
Objective specification	This data sheet contains target or goal specifications for product development.
Preliminary specification	This data sheet contains preliminary data; supplementary data may be published later.
Product specification	This data sheet contains final product specifications.
Limiting values	
Limiting values given are in accordance with the Absolute Maximum Rating System (IEC 134). Stress above one or more of the limiting values may cause permanent damage to the device. These are stress ratings only and operation of the device at these or at any other conditions above those given in the Characteristics sections of the specification is not implied. Exposure to limiting values for extended periods may affect device reliability.	
Application information	
Where application information is given, it is advisory and does not form part of the specification.	

20 LIFE SUPPORT APPLICATIONS

These products are not designed for use in life support appliances, devices, or systems where malfunction of these products can reasonably be expected to result in personal injury. Philips customers using or selling these products for use in such applications do so at their own risk and agree to fully indemnify Philips for any damages resulting from such improper use or sale.

21 PURCHASE OF PHILIPS I²C COMPONENTS

Purchase of Philips I²C components conveys a license under the Philips' I²C patent to use the components in the I²C system provided the system conforms to the I²C specification defined by Philips. This specification can be ordered using the code 9398 393 40011.
