

20W Stereo Digital Class-D Audio Power Amplifier with EQ and DRC

Features

- **Operating Voltage: 8.0V~24V for PVDD**
– 3.0V~3.6V for DVDD and AVDD
- **High Efficiency Class-D Operation Eliminate the Need of Heatsinks**
- **Digital Serial Audio Input (Stereo Output)**
- **I²C Control Interface**
- **Sampling Rate can Support from 32kHz to 192kHz**
- **Separated Volume Control from 24dB to Mute**
- **Soft Mute (50% Duty Cycle)**
- **Programmable Dynamic Range Compression**
– Power Limiter
– Speaker Protection
– Night-Mode Listening
- **Programmable Biquads for Speaker EQ**
- **Shutdown and Mute Function**
- **Thermal and Over-Current Protections with Auto-Recovery**
- **Space Saving Package TQFP7x7-48P**
- **Lead Free and Green Devices Available (RoHS Compliant)**

Applications

- LCD TV

Simplified Application Circuit

General Description

The APA3160 is a digital input, stereo, high efficiency, Class-D audio amplifier available in a TQFP7x7-48P package.

The APA3160 accepts the digital serial audio data and using the digital audio processor to convert the audio data becomes the stereo Class-D output speaker amplifier. This provides the seamless integration between the codec and the speaker amplifier.

The APA3160 is a slave device receiving clocks from external source, and the Class-D's PWM switching frequency is 352.8kHz for the sampling rate 44.1kHz or 384 kHz for sampling 48kHz, depend on the input signal's sampling rate.

Pin Configuration

ANPEC reserves the right to make changes to improve reliability or manufacturability without notice, and advise customers to obtain the latest version of relevant information to verify before placing orders.

Ordering and Marking Information

<p>APA3160 □□□□-□□ □</p>  <p> Assembly Material Handling Code Temperature Range Package Code </p>	<p> Package Code QCA : TQFP7x7-48P Operating Ambient Temperature Range I : -40 to 85 °C Handling Code TR : Tape & Reel Assembly Material G : Halogen and Lead Free Device </p>
<p>APA3160 QCA :</p> 	<p>XXXXX - Date Code</p>

Note : ANPEC lead-free products contain molding compounds/die attach materials and 100% matte tin plate termination finish; which are fully compliant with RoHS. ANPEC lead-free products meet or exceed the lead-free requirements of IPC/JEDEC J-STD-020D for MSL classification at lead-free peak reflow temperature. ANPEC defines “Green” to mean lead-free (RoHS compliant) and halogen free (Br or Cl does not exceed 900ppm by weight in homogeneous material and total of Br and Cl does not exceed 1500ppm by weight).

Absolute Maximum Ratings (Note 1)

Symbol	Parameter	Rating	Unit
	Supply Voltage (PVDD_X to PGND_XX)	-0.3 to 26	V
	Supply Voltage (DVDD to DVSS)	-0.3 to 3.6	
	Supply Voltage (AVDD to AVSS)	-0.3 to 3.6	
	Input Voltage (MCLK to AVSS)	-0.5 to AVDD+2.5	
	Input Voltage (SD, RST, LRCLK, SCLK, SDIN, SDA, SCL to DVSS)	-0.5 to DVDD+2.5	
	Input Voltage (OUT_X to PGND_XX)	-0.3 to +32	
	Input Voltage (XBS to PGND_XX)	-0.3 to +43	
	Input Voltage (AVSS, DVSS, AGND to PGND_XX)	-0.3 to +0.3	
T _J	Maximum Junction Temperature	150	°C
T _{STG}	Storage Temperature Range	-65 to +150	°C
T _{SDR}	Soldering Temperature Range, 10 seconds	260	°C
P _D	Power Dissipation	Internally Limited	W

Note 1: Absolute Maximum Ratings are those values beyond which the life of a device may be impaired. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

Thermal Characteristics

Symbol	Parameter	Typical Value	Unit
θ _{JA}	Junction-to-Ambient Resistance in Free Air ^(Note 2)	25	°C/W
	TQFP7x7-48P		
θ _{JC}	Junction-to-Case Resistance in Free Air ^(Note 3)	-	°C/W
	TQFP7x7-48P		

Note 2: θ_{JA} is measured with the component mounted on a high effective thermal conductivity test board in free air. The exposed pad of TQFP7X7-48P is soldered directly on the PCB.

Note 3: The case temperature is measured at the center of the exposed pad on the underside of the TQFP7X7-48P package.

Recommended Operating Conditions

Symbol	Parameter	Range		Unit	
		Min.	Max.

Block Diagram

Typical Application Circuit

Function Description

Clock And PLL

The APA3160 is a slave device and receives signals from MCLK, SCLK, and LRCLK. The digital audio processor (DAP) provides all sample rates and MCLK rates which defined in the clock control register.

The APA3160 checks to verify that SCLK is a particular value of $32f_s$, $48f_s$, or $64f_s$. The DAP only provides a $1 \times f_s$ LRCLK. The timing relationship of these clocks to SDIN is shown in subsequent sections.

Serial Data Interface

Serial data is an input transmitted to SDIN. The PWM outputs are derived from SDIN. Besides, the APA3160 DAP receives left-justified, right-justified, and I²S serial data formats with 16, 20, or 24 bit.

PWM Section

The APA3160 DAP device is a high power efficiency and high-performance digital audio reproduction. A noise shaper is used to increase dynamic range and SNR in the audio band. The PWM section receives 24bit PCM data from the DAP and outputs two BTL PWM audio output channels.

The PWM section has individual channel dc blocking filters that can be enabled and disabled. The low pass filter cutoff frequency is less than 1Hz. Besides, the PWM section includes individual channel de-emphasis filters for 44.1 and 48 kHz and can be enabled and disabled.

The adjustable maximum modulation limit of PWM section is from 93.8% to 98.4%.

I²C Compatible Serial Control Interface

The APA3160 DAP receives commands from a system controller through an I²C serial control slave interface. The serial control interface supports both normal-speed 100kHz and high-speed 400kHz operations without waiting states. As an added feature, even though the MCLK is absent, the interface operates.

For status registers, the serial control interface provides both single-byte and multi-byte read and write operations; and for the general control registers, they associated with the PWM.

Function Description (Cont.)

Serial Interface Control And Timing

I²S Timing

I²S timing uses LRCLK to define the data for the left channel and the right channel when the data being transmitted. For the left channel, the LRCLK is low; for the right channel, the LRCLK is high. A bit clock running at $32, 48, \text{ or } 64 \times f_s$ is used to clock in the data. When the LRCLK signal changes state, there is a delay of one bit clock from the time which the first bit of data on the data lines. The data is written MSB first and is valid on the rising edge of bit clock. The DAP masks unused trailing data bit positions.

Figure 1. I²S 64 f_s Format

Figure 2. I²S 48 f_s Format

Figure 3. I²S 32 f_s Format

Function Description (Cont.)

Left-Justified

Left-justified (LJ) timing uses LRCLK to define the data for the left channel and the right channel when the data being transmitted. For the left channel, the LRCLK is high; for the right channel, the LRCLK is low. A bit clock running at 32 , 48 , or $64 \times f_s$ is used to clock in the data. The first bit of data appears on the data lines when LRCLK toggles. The data is written MSB first and is valid on the rising edge of the bit clock. The DAP masks unused trailing data bit positions.

Figure 4. Left-Justified 64 f_s Format

Figure 5. Left-Justified 48 f_s Format

Figure 6. Left-Justified 32 f_s Format

Function Description (Cont.)

Right-Justified

Right-justified (RJ) timing uses LRCLK to define the data for the left channel and the right channel when the data being transmitted. For the left channel, the LRCLK is high; for the right channel, the LRCLK low. A bit clock running at $32, 48, \text{ or } 64 \times f_s$ is used to clock in the data. After LRCLK toggles, for 24bit data, the first bit of data appears on the data 8 bit-clock. In RJ mode, the LSB of data is always clocked by the last bit clock before LRCLK transitions. The data is written MSB first and is valid on the rising edge of bit clock. The DAP masks unused leading data bit positions.

Figure 7. Right-Justified 64 f_s Format

Figure 8. Right-Justified 48 f_s Format

Figure 9. Right-Justified 32 f_s Format

Function Description (Cont.)

I²C Serial Control Interface

The APA3160 DAP has a bidirectional I²C interface that compatible with the I²C (Inter IC) bus protocol. Besides, it provides both 100kHz and 400kHz data transfer rates to single and multiple bytes write and read operations.

This is a slave only device, and it doesn't support a multi-master bus environment or wait state insertion. The function of the control interface is to read device status and to program the registers of the device.

The DAP supports the standard-mode I²C bus operation (100kHz maximum) and the fast I²C bus operation (400kHz maximum). Without I²C wait cycles, the DAP performs I²C operations.

General I²C Operation

The I²C bus uses SDA (data) and SCL (clock) to communicate between integrated circuits in a system. Data is transferred on the bus serially one bit at a time. With the most significant bit (MSB) transferred first, the address and data can be transferred in byte (8bit) format. In addition, each byte transferred on the bus is acknowledged by the receiving device with an acknowledge bit. Each transfer operation begins with the master device driving a start condition on the bus and ends with the master device driving a stop condition on the bus.

The bus uses transitions on the SDA when the clock is high to indicate start and stop conditions. A high-to-low transition on SDA indicates a start, and a low-to-high transition indicates a stop. Normal data bit transitions must occur within the low time of the clock. These conditions are shown in Figure 10. The master generates the 7bit slave address and the read/write (R/W) bit to open communication with another device and then waits for an acknowledge condition. The APA3160 holds SDA low during the acknowledge clock to indicate an acknowledgment. When this occurs, the master transmits the next byte of the sequence.

Each device is addressed by a unique 7bit slave address plus R/W bit (1 byte). All compatible devices share the same signals via a bidirectional bus using a wired-AND connection. An external pull-up resistor must be used for the SDA and SCL signals to set the high level for the bus.

Figure 10. Typical I²C Sequence

There is no limit on the number of bytes that can be transmitted between start and stop conditions. When the last word transfers, the master generates a stop condition to release the bus. A generic data transfer sequence is shown in Figure 10.

The 7bit address for APA3160 is 0011 010 (0x34). APA3160 address can be changed from 0x34 to 0x38 by writing 0x38 to device address register 0xF9.

Function Description (Cont.)

Single- and Multiple-Byte Transfers

The serial control interface supports single-byte and multiple-byte (R/W) operations for sub-addresses 0x00 to 0x1F. However, for the sub-addresses 0x20 to 0xFF, the serial control interface supports only multiple-byte read/write operations (in multiples of 4 bytes).

During multiple-byte read operations, the DAP responds with data, a byte at a time, starting at the sub-address assigned, as long as the master device continues to respond with acknowledges. If a particular sub-address does not contain 32 bits, the unused bits are read as logic 0.

During multiple-byte write operations, the DAP compares the number of bytes transmitted to the number of bytes that are required for each specific sub-address.

Supplying a sub-address for each sub-address transaction is referred to as random I²C addressing. The APA3160 also supports sequential I²C addressing. For write transactions, if a sub-address is issued and followed by data for that sub-address and the 15 sub-addresses that follow, a sequential I²C write transaction has taken place, and the data for all 16 sub-addresses is successfully received by the APA3160. For I²C sequential write transactions, the sub-address then serves as the start address, and the amount of data subsequently transmitted, before a stop or start is transmitted, determines how many sub-addresses are written. As was true for random addressing, sequential addressing requires that a complete set of data be transmitted. If only a partial set of data is written to the last sub-address, the data for the last sub-address is discarded. However, if all other data written is accepted, only the incomplete data is discarded.

Single-Byte Write

As shown in Figure 11, a single-byte data write transfer begins with the master device transmitting a start condition followed by the I²C device address and the R/W bit. The R/W bit determines the direction of the data transfer. For a write data transfer, the R/W bit will be a 0. After receiving the correct I²C device address and the R/W bit, the DAP responds with an acknowledge bit. And then, the master transmits the address byte or bytes corresponding to the APA3160 internal memory address being accessed. After receiving the address byte, the APA3160 responds with an acknowledge bit again. Next, the master device transmits the data byte to be written to the memory address being accessed. After receiving the data byte, the APA3160 again responds with an acknowledge bit. Finally, the master device transmits a stop condition to complete the single-byte data write transfer.

Figure 11. Single-Byte Write Transfer

Function Description (Cont.)

Multiple-Byte Write

A multiple-byte data write transfer is identical to a single-byte data write transfer except that multiple data bytes are transmitted by the master device to the DAP as shown in Figure 12. After receiving each data byte, the APA3160 responds with an acknowledge bit.

Figure 12. Multiple-Byte Write Transfer

Single-Byte Read

As shown in Figure 13, a single-byte data read transfer begins with the master device transmitting a start condition followed by the I²C device address and the R/W bit. For the data read transfer, both a write followed by a read are actually done. Initially, a write is done to transfer the address byte or bytes of the internal memory address to be read. As a result, the R/W bit becomes a 0. After receiving the APA3160 address and the read/write bit, APA3160 responds with an acknowledge bit. Besides, after sending the internal memory address byte or bytes, the master device transmits another start condition followed by the APA3160 address and the read/write bit again. This time the read/write bit becomes a 1, indicating a read transfer. After receiving the address and the read/write bit, the APA3160 again responds with an acknowledge bit. And then, the APA3160 transmits the data byte from the memory address being read. After receiving the data byte, the master device transmits a not acknowledge followed by a stop condition to complete the single byte data read transfer.

Figure 13. Single-Byte Read Transfer

Multiple-Byte Read

A multiple-byte data read transfer is identical to a single-byte data read transfer except that multiple data bytes are transmitted by the APA3160 to the master device as shown in Figure 14. Except for the last data byte, the master device responds with an acknowledge bit after receiving each data byte.

Figure 14. Multiple-Byte Read Transfer

Function Description (Cont.)

Dynamic Range Control (DRC)

The DRC scheme has a single threshold, offset, and slope (all programmable). There is one ganged DRC for the left/right channels.

The DRC input/output diagram is shown in Figure 15.

Professional-quality dynamic range compression automatically adjusts volume to flatten volume level.

- One DRC for left/right.
- The DRC has adjustable threshold, offset, and compression levels.
- Programmable energy, attack, and decay time constants.
- Transparent compression: compressors can attack fast enough to avoid apparent clipping before engaging, and decay times can be set slow enough to avoid pumping.

Figure 15. Dynamic Range Control

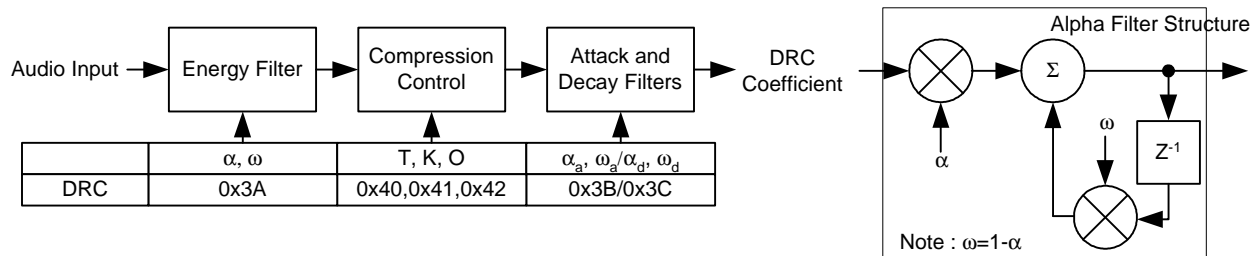

Figure 16. DRC Structure

Biquad Structure

All biquads use a 2nd order IIR filter structure as shown below. Each biquad has 3 coefficients on the direct path (b_0, b_1, b_2) and 2 coefficients on feedback path (a_1 and a_2) which is shown in the diagram.

Figure 17. Biquad Filter

Function Description (Cont.)

26Bit 3.23 Number Format

All mixer gain coefficients are 26 bit coefficients and use a 3.23 number format. Numbers formatted as 3.23 numbers means that there are 3 bits to the left of the decimal point and 23 bits to the right of the decimal point. This is shown in Figure 18.

Figure 18. 3.23 Format

The decimal value of a 3.23 format number can be found by following the weighting and is shown in Figure 18. If the MSB is logic 0, the number is a positive number, and the weighting shown yields the correct number. If the MSB is a logic 1, and then the number is a negative number. In this case, every bit must be inverted, a 1 added to the result, and then the weighting shown in Figure 19 applied to obtain the magnitude of the negative number.

Figure 19. Conversion Weighting Factors 3.23 Format to Floating Point

Gain coefficients, entered via the I²C bus, must be entered as 32 bit binary numbers. The format of the 32 bit number (4 byte or 8 digit hexadecimal number) is shown in Figure 20.

Figure 20. Alignment of 3.23 Coefficient in 32Bit I²C Word

Function Description (Cont.)

Sample Calculation for 3.23 Format

Parameter	Description	APA3160			Unit
		Min.	Typ.	Max.	
$t_{VDDH-DL}$	Time digital inputs must remain low after AVDD/DVDD goes above 3V	0	-	-	μs
$t_{DL-VDDH}$	Time digital inputs must be low before AVDD/DVDD goes below 3V	0	-	-	
$t_{VDDH-PVDDL}$	Time PVDD/AVCC remains below 7.5V after AVDD/DVDD goes above 3V	100	-	-	
$t_{PVDDL-VDDH}$	Time PVDD/AVCC must be below 7.5V before AVDD/DVDD goes below 3V	0	-	-	
$t_{PVDDH-I2C}$	Time PVDD/AVCC must be above 10V before I ² C commands may address device	10	-	-	
$t_{RL-PVDDH}$	Time PVDD/AVCC must remain above 10V after RST goes low	2	-	-	
t_{RH-I2C}	Time RESET must be high before I ² C commands may address device	13.5	-	-	ms
t_{DV-RH}	Time digital inputs must be valid (driven as recommended) before RST goes high	100	-	-	μs
t_{RL-DV}	Time digital inputs must remain valid (driven as recommended) after RST goes low	2	-	-	
$t_{autodetect}$	Auto-detect completion wait time (given stable and valid clocks) before issuing further commands	50	-	-	ms
t_{exitSD}	Exit shutdown wait time before issuing further commands to device (t start given by register 0x1A)	$1+1.3 \times t_{start}$	-	-	
$t_{enterSD}$	Enter shutdown wait time before issuing further commands to device (t stop given by register 0x1A)	$1+1.3 \times t_{stop}$	-	-	
t_{POR}	Power-on-reset wait time after 1st trim following AVDD/DVDD power-up (t start given by register 0x1A) (does not apply to trim commands following subsequent resets)	$240 + 1.3 \times t_{start}$	-	-	

Figure 22. Power Loss Sequence

Function Description (Cont.)

Recommended Use Model (Cont.)

Parameter	Description	APA3160			Unit
		Min.	Typ.	Max.	
t _{RL-DV}	Time digital inputs must remain valid (driven as recommended) after $\overline{\text{RST}}$ goes low	2	-	-	μs
t _{DL-VDDH}	Time digital inputs must be low before AVDD/DVDD goes below 3V	0	-	-	
t _{RL-PVDDH}	Time PVDD/AVCC must remain above 10V after $\overline{\text{RST}}$ goes low	2	-	-	
t _{PVDDL-VDDH}	Time PVDD/AVCC must be below 7.5V before AVDD/DVDD goes below 3V	0	-	-	

Recommended Command Sequences

The DAP has two groups of commands. One set is for configuration and is intended for use only during initialization. The other set has built-in click and pop protection and may be used during normal operation while audio is streaming. The following supported command sequences illustrate how to initialize, operate, and shutdown the device.

Initialization Sequence

Use the following sequence to power-up and initialize the device:

1. Hold all digital inputs low and ramp up AVDD/DVDD to at least 3V.
2. Initialize digital inputs and PVDD supply as follows:
 - Drive $\overline{\text{RST}}=0$, $\overline{\text{SD}}=1$, and other digital inputs to their desired state while ensuring that all are never more than 2.5V above AVDD/DVDD. Provide stable and valid I²S clocks (MCLK, LRCLK, and SCLK). Wait at least 100μs, drive $\overline{\text{RST}}=1$, and wait at least another 13.5ms.
 - Ramp up PVDD to at least 8V while ensuring that it remains below 6V for at least 100μs after AVDD/DVDD reaches 3V. Then wait at least another 10μs.
3. Configure the DAP via I²C (see Users's Guide for typical values): biquads (0x29-36)DRC parameters (0x3A-3C, 0x40-42, and 0x46) Bank select (0x50).
4. Configure remaining registers.
5. Exit shutdown (sequence defined below).

Normal Operation

The following are the only events supported during normal operation:

- (a) Writes to master/channel volume registers
- (b) Writes to soft mute register
- (c) Enter and exit shutdown (sequence defined below)
- (d) Clock errors and rate changes

Note: Events (c) and (d) are not supported for 240ms+1.3x_{t₀} after trim following AVDD/DVDD power up ramp (where T_{start} is specified by register 0x1A).

Function Description (Cont.)

Shutdown Sequence

Enter:

1. Ensure I²S clocks have been stable and valid for at least 50ms.
2. Write 0x40 to register 0x05.
3. Wait at least $1\text{ms} + 1.3t_{\text{stop}}$ (where t_{stop} is specified by register 0x1A).
4. Once in shutdown, stable clocks are not required while device remains idle.
5. If desired, reconfigure by ensuring that clocks have been stable and valid for at least 50ms before returning to step 4 of initialization sequence.

Exit:

1. Ensure I²S clocks have been stable and valid for at least 50ms.
2. Write 0x00 to register 0x05 (exit shutdown command may not be serviced for as much as 240ms after trim following AVDD/DVDD powerup ramp).
3. Wait at least $1\text{ms} + 1.3t_{\text{start}}$ (where t_{start} is specified by register 0x1A).
4. Proceed with normal operation.

Power-down Sequence

Use the following sequence to power-down the device and its supplies:

1. If time permits, enter shutdown (sequence defined above); else, in case of sudden power loss, assert $\overline{\text{SD}}=0$ and wait at least 2ms.
2. Assert $\overline{\text{RST}}=0$.
3. Drive digital inputs low and ramp down PVDD supply as follows:
 - Drive all digital inputs low after $\overline{\text{RST}}$ has been low for at least $2\mu\text{s}$.
 - Ramp down PVDD while ensuring that it remains above 8V until $\overline{\text{RST}}$ has been low for at least $2\mu\text{s}$.
4. Ramp down AVDD/DVDD while ensuring that it remains above 3V until PVDD is below 6V and that it is never more than 2.5V below the digital inputs.

Function Description (Cont.)

Clock Control Register (0x00)

The clocks and data rates are automatically determined by the APA3160. The clock control register contains the auto-detected clock status. Bits D7-D5 reflect the sample rate. Bits D4-D2 reflect the MCLK frequency.

Table 2. Clock Control Register (0x00)

D7	D6	D5	D4	D3	D2	D1	D0	FUNCTION
0	0	0	-	-	-	-	-	$f_s=32\text{kHz}$ sample rate

-	-	-	1	1	1	-	-	Reserved ⁽⁴⁾
-	-	-	-	-	-	0	-	Reserved ⁽⁴⁾
-	-	-	-	-	-	-	0	Reserved ⁽⁴⁾

Note (4): Reserved registers should not be accessed.

Note (5): Italic is default.

Note (6): Only available for 44.1kHz and 48kHz rates.

Note (7): Rate only available for 32/44.1/48kHz sample rates.

Note (8): Not available at 8kHz.

Device Id Register (0x01)

The device ID register contains the ID code for the firmware revision.

Table 3. General Status Register (0x01)

D7	D6	D5	D4	D3	D2	D1	D0	FUNCTION
X	-	-	-	-	-	-	-	Reserved
-	0	0	0	0	0	0	0	Identification code

Note: Italic is default.

Function Description (Cont.)

Error Status Register (0x02)

The error bits are sticky and are not cleared by the hardware. This means that the software must clear the register (write zeroes) and then read them to determine if they are persistent errors. Error Definitions:

MCLK Error : MCLK frequency is changing. The number of MCLKs per LRCLK is changing.

SCLK Error: The number of SCLKs per LRCLK is changing.

LRCLK Error: LRCLK frequency is changing.

Table 4. Error Status Register (0x02)

D7	D6	D5	D4	D3	D2	D1	D0	FUNCTION
1	-	-	-	-	-	-	-	MCLK error
-	1	-	-	-	-	-	-	PLL auto clock error
-	-	1	-	-	-	-	-	SCLK error
-	-	-	1	-	-	-	-	LRCLK error
-	-	-	-	1	-	-	-	Reserved
-	-	-	-	-	1	-	-	Reserved
-	-	-	-	-	-	1	-	Over temperature warning (sets around 145°C) POR error, OCP, thermal shutdown error
0	0	0	0	0	0	0	0	No errors

Note: Italic is default.

System Control Register 1 (0x03)

The system control register 1 has several functions:

Bit D7: If 0, the dc-blocking filter for each channel is disabled. If 1, the dc-blocking filter (-3dB cutoff < 1Hz) for each channel is enabled (default).

Bit D5: If 0, use soft unmute on recovery from clock error. This is a slow recovery. Unmute takes same time as volume ramp defined in reg 0x0E. If 1, use hard unmute on recovery from clock error (default). This is a fast recovery, a single step volume ramp

Bits D1-D0: Select de-emphasis.

Table 5. System Control Register 1 (0x03)

D7	D6	D5	D4	D3	D2	D1	D0	FUNCTION

Note: Italic is default.

Function Description (Cont.)

Serial Data Interface Register (0x04)

As shown in Table 6, the APA3160 supports 9 serial data modes. The default is 24bit, I²S mode.

Table 6. Serial Data Interface Control Register (0x04) Format

D7	D6	D5	D4	D3	D2	D1	D0	Word Length	Receive Serial Data Interface Format

Volume Configuration Register (0x0E)

Bits Volume slew rate (Used to control volume change and MUTE ramp rates). These bits control the D2-D0: number of steps in a volume ramp. Volume steps occur at a rate that depends on the sample rate of the I²S data as follows.

Sample Rate (kHz)	Approximate Ramp Rate
8/16/32	125µs/step
11.025/22.05/44.1	90.7µs/step
12/24/48	83.3µs/step

Note: Italic is default.

Start/Stop Period Register (0x1A)

This register is used to control the soft-start and soft-stop period following an enter/exit all channel shut down command or change in the \overline{SD} state. This helps reduce pops and clicks at start-up and shutdown. The times are only approximate and vary depending on device activity level and I²S clock stability.

Pwm Output Mux Register (0x25)

This DAP output mux selects which internal PWM channel is output to the external pins. Any channel can be output to any external output pin.

Bits D21-D20: Selects which PWM channel is output to OUT_A

Bits D17-D16: Selects which PWM channel is output to OUT_B

Bits D13-D12: Selects which PWM channel is output to OUT_C

Bits D09-D08: Selects which PWM channel is output to OUT_D

Note that channels are enclosed so that channel 1=0x00, channel 2=0x01, channel 1=0x02, and channel 2=0x03.

Function Description (Cont.)

Error Reporting

Any fault resulting in device shutdown is signaled by the $\overline{\text{ERROR}}$ pin going low (see Table 18). A sticky version of this pin is available on D1 of register 0X02.

Table 16. $\overline{\text{ERROR}}$ Output States

Fault Description	Error
0	Over-Current (OC) or Under-Voltage (UVP) or Over-Temperature (OTP)
1	No faults (normal operation)

Over-Current (OC) Protection With Current-Limiting

The device has independent, fast-reacting current detectors on all high-side and low-side power-stage FETs. The detector outputs are closely monitored by two protection systems. The first protection system controls the power stage in order to prevent the output current further increasing, i.e., it performs a cycle-by-cycle current-limiting function, rather than prematurely shutting down during combinations of high-level music transients and extreme speaker load impedance drops. If the high-current condition situation persists, i.e., the power stage is being overloaded, a second protection system triggers a latching shutdown, resulting in the power stage being set in the high-impedance (Hi-Z) state. The device returns to normal operation once the fault condition (i.e., a short circuit on the output) is removed. Current limiting and overcurrent protection are not independent for half-bridges.

That is, if the bridge-tied load between half-bridges A and B causes an overcurrent fault, half-bridges A, B, C, and D are shut down.

Over-Temperature Protection

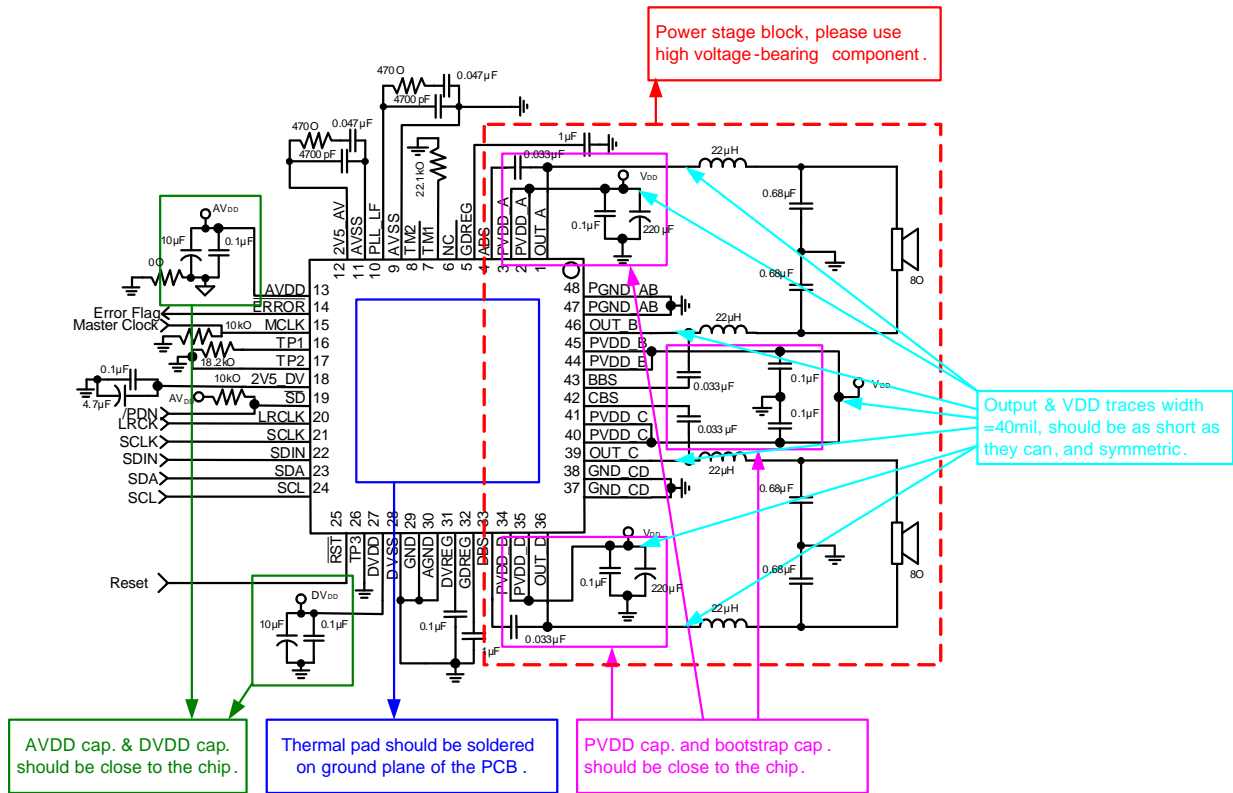

The APA3160 has over-temperature protection system. If the device junction temperature exceeds 150°C (nominal), the device is put into thermal shutdown, resulting in all half-bridge outputs being set in the high-impedance (Hi-Z) state and FAULT being asserted low. The APA3160 recovers automatically once the temperature drops approximately 30°.

Under-Voltage Protection (UVP) and Power-On-Reset (POR)

The UVP and POR circuits of the APA3160 fully protect the device in any power-up/down and brownout situation. While powering up, the POR circuit resets the overload circuit (OLP) and ensures that all circuits are fully operational when the PVDD and AVDD supply voltages reach 7.6V and 2.7V, respectively. Although PVDD and AVDD are independently monitored, a supply voltage drop below the UVP threshold on AVDD or either PVDD pin results in all half-bridge outputs immediately being set in the high-impedance (Hi-Z) state and ERROR being asserted low.
